

Text Splitter Practice Document

Artificial Intelligence is a field of computer science that focuses on creating systems that can perform tasks that normally require human intelligence.

Machine learning is a part of artificial intelligence. It allows computers to learn patterns from data and make predictions or decisions without being explicitly programmed for every situation.

Natural Language Processing, commonly called NLP, helps computers understand, process, and generate human language. Examples include chatbots, text classification, translation, and sentiment analysis.

LangChain is a framework that can be used to build applications powered by language models. It provides components for prompts, models, output parsers, document loaders, text splitters, embeddings, and retrieval.

Text splitting is important in Retrieval Augmented Generation applications because large documents are divided into smaller chunks before they are converted into embeddings and stored in a vector database.

CharacterTextSplitter is one of the text splitters available for dividing text into chunks. Important parameters include `chunk_size`, `chunk_overlap`, and `separator`.

For example, a `chunk_size` of 100 means that the splitter tries to create chunks around 100 characters in size. A `chunk_overlap` of 20 means that neighboring chunks can share some text.

Practicing different separators and chunk sizes helps you understand how documents are divided before they are used in a RAG pipeline.
